

VEHICLE IMPACT ON STRUCTURES AUTOMATED RISK ASSESSMENT

How FME extracts NZTA CAS data from ArcGIS Online, compares it against Snowflake event records, and applies user-defined rules to calculate structure risk ratings

FME

ArcGIS Online

Snowflake

Vijay Paul | Senior Geospatial Specialist – Systems

FME story in one line

Turn frequently updated, high-volume source data into a transparent and repeatable structure risk rating.

Public safety • Network resilience • Repeatable prioritisation

Why automate the assessment?

New data monthly, weekly, nightly

CAS data is regularly updated and contains hundreds of thousands of records. Manually re-reading everything increases runtime and competes with other FME Flow automations.

Speed limit data is extracted from NZSLR nightly basis.

Transpower assets could receive an update any time.

Multiple systems

Crash data, structure assets, road context, speed limits, incident records and public-safety criticality must be brought together consistently.

Repeatable decisions

Clear, visible rules let us rank every structure on the same basis, instead of reacting to whichever one was impacted by a vehicle.

Here automation turns the data we already have into risk we can act on.

Where the data comes from ?

CRASH HISTORY

NZTA CAS

Crash locations, severity and crash attributes

Snowflake incidents

Recorded vehicle-to-pole incidents

WHAT WE OWN

Structure assets

Commissioned structures from the enterprise geodatabase

Public safety criticality

Enterprise criticality attribute used in scoring

ROAD ENVIRONMENT

Road centrelines

Proximity between structures and the road network

Speed limits

Road speed context near structures

Design principle: keep source ownership intact, then integrate only what the risk model needs.

Efficient extraction of CAS data

The extraction pattern should minimise payload, maintain traceability and remain resilient as the source grows.

- 1 Query** Feature Reader filter records at source with a WHERE clause when appropriate.
- 2 Clip** Pass an envelope around the line of interest so only nearby CAS records are retrieved.
- 3 Standardise** Retain required attributes and create a stable identifier.
- 4 Validate** Check schema, geometry and expected record behaviour.

The screenshot displays an FME workflow for extracting CAS data. It includes a 'Constraints' panel with 'Feature Types to Read' set to 'CAS_Data_public' and a 'WHERE Clause' of 'crashYear BETWEEN 2025 AND 2026'. Below this is a map showing a red line of interest. The workflow consists of three main components: 'HTTPCaller', 'JSONFragmenter_2', and 'DateTimeStamper'. The 'HTTPCaller' component has a 'Clip to Initiator Envelope' checkbox checked. The 'JSONFragmenter_2' component has 'Input', 'Fragments', and '<Rejected>' outputs. The 'DateTimeStamper' component has 'Input' and 'Output' outputs. A 'Test Response Preview' window shows the output as a JSON object with a 'count' of 696879.

Constraints

Feature Types to Read: CAS_Data_public

WHERE Clause: crashYear BETWEEN 2025 AND 2026

Feature Types to Read: CAS_Data_public

WHERE Clause: 1=1

Spatial Filter: <No Spatial Filter>

Clip to Initiator Envelope: ☒

HTTPCaller

JSONFragmenter_2

DateTimeStamper

Test Response Preview

```
{
  "count": 696879
}
```

Querying incident data from Snowflake

Connecting securely, then pulling back only the incident records the model needs.

Connection Property	Value
proxyPort	80
nonProxyHosts	*.transpower.co.nz
tracing	all
user	FME_PRD_LOCAL
private_key_file	\\PrdApp98\FME_workbenches\FME_PROD_LOCAL_rsa_key.p8

SQLCreator_2

- <Schema>
- Result
 - SFIR
 - LOCATION
 - LOGYEAR
 - LOGDATE
 - DESCRIPTION
 - WONUM
 - TICKETID
 - SOURCE

SQLCreator Parameters

Database

- Format: Snowflake Non-Spatial
- Connection: Vp-prod
- Parameters...
- Coordinate System: Unknown

General

- SQL Statement: WITH seed AS (...)
- Attributes to Expose: SFIR, LOCATION, LOGYEAR, LOGDATE, DESCRIPTION, WONUM, ...

```
204
205 /*
206 Fill LOCATION from DESCRIPTION when LOCATION is missing
207 - Prefer code after "STRUCTURE ..." if present
208 - Otherwise first standard code anywhere
209 - Handle "ASH-TIM A0444" -> "ASH-TIM-A0444"
210 - Normalize underscores/spaces -> hyphen; strip -00/-10
211 - Convert XXX-TEE-A56 -> XXX-TEE-AT56
212 ===== */
213 loc_enriched AS (
214 SELECT
215 sfir,
216
```

Measurements we derive from the data

Road proximity

Find structures near road centrelines.

Intersection proximity

Measure distance to nearby intersections.

Crash proximity

Associate crashes occurring near structures.

Incident linkage

Connect recorded pole-impact events.

Asset context

Add speed and criticality attributes.

Each relationship creates a measurable risk signal for the rules engine.

Rules we apply to those measurements

Crash history

Crash within 20 m
Severe or Fatal crash nearby
Crash involving post or pole

Road exposure

Within 5 m of centreline
Within 10 m of centreline
Higher nearby speed limit

Network consequence

Public safety criticality available
Recorded internal incident
Asset-level context

Example: how a structure receives a rating

Within 5 m of road centreline	+2
Crash recorded within 20 m	+1
Nearby speed limit greater than 80 km/h	+2
Public safety criticality populated	+1
In a frequent crash area	+2
TOTAL	8

ILLUSTRATIVE
RATING

HIGH

Rating thresholds should be agreed
and governed by the business.

From risk score to hotspot insight

Structure Risk Rating	
Device Position	BPE-MHO-A0588
Structure Type	Single Circuit Single Pole
Status	COMMISSIONED
Public safety (NZD)	\$314,333
Distance from centreline (m)	8.24
Speed Limit	100
Intersection 50m	Yes
Intersection 100m	Yes
Crashes involving a pole or post	No
Crashes within 20m	1
Severe crash within 20m	1
Risk	8
Street view	View

Decision-ready outputs

- Structure-level risk score and rating
- Filtered CAS layer near structures
- Interactive map for exploration
- Hotspot view for geographic clustering
- Repeatable refresh through FME Flow

Where FME automation pays off

01

FLEXIBLE REFRESH

Runs weekly, on demand when needed, and tells us if it fails.

02

CONSISTENT METHOD

Apply the same spatial logic and rules every run.

03

TRACEABLE RISK

Show which rule signals contribute to each score.

04

FOCUSED ACTION

Prioritise investigation and mitigation using risk evidence.

Challenges along the way

Crash location accuracy

Points sit on the road, so crashes are matched by a spatial join within a buffer.
Direction of travel, and which side of the road the crash happened on, is not always recorded.

Agreeing thresholds

Set distances and severity with the Risk and Health and Safety team.

Key pair authentication

Fiddly to set up but needed once MFA became the preferred pattern.

Data source availability

Checks in FME to make sure all datasources are available prior to the schedule run.

The webapp is built. The next step is getting it used widely and sharing what it shows.

REFINE

More data, fine tune rules, sharper risk

SCALE

Risk across line sections, not just towers

PARTNER

Waka Kotahi, EDBs and local councils
